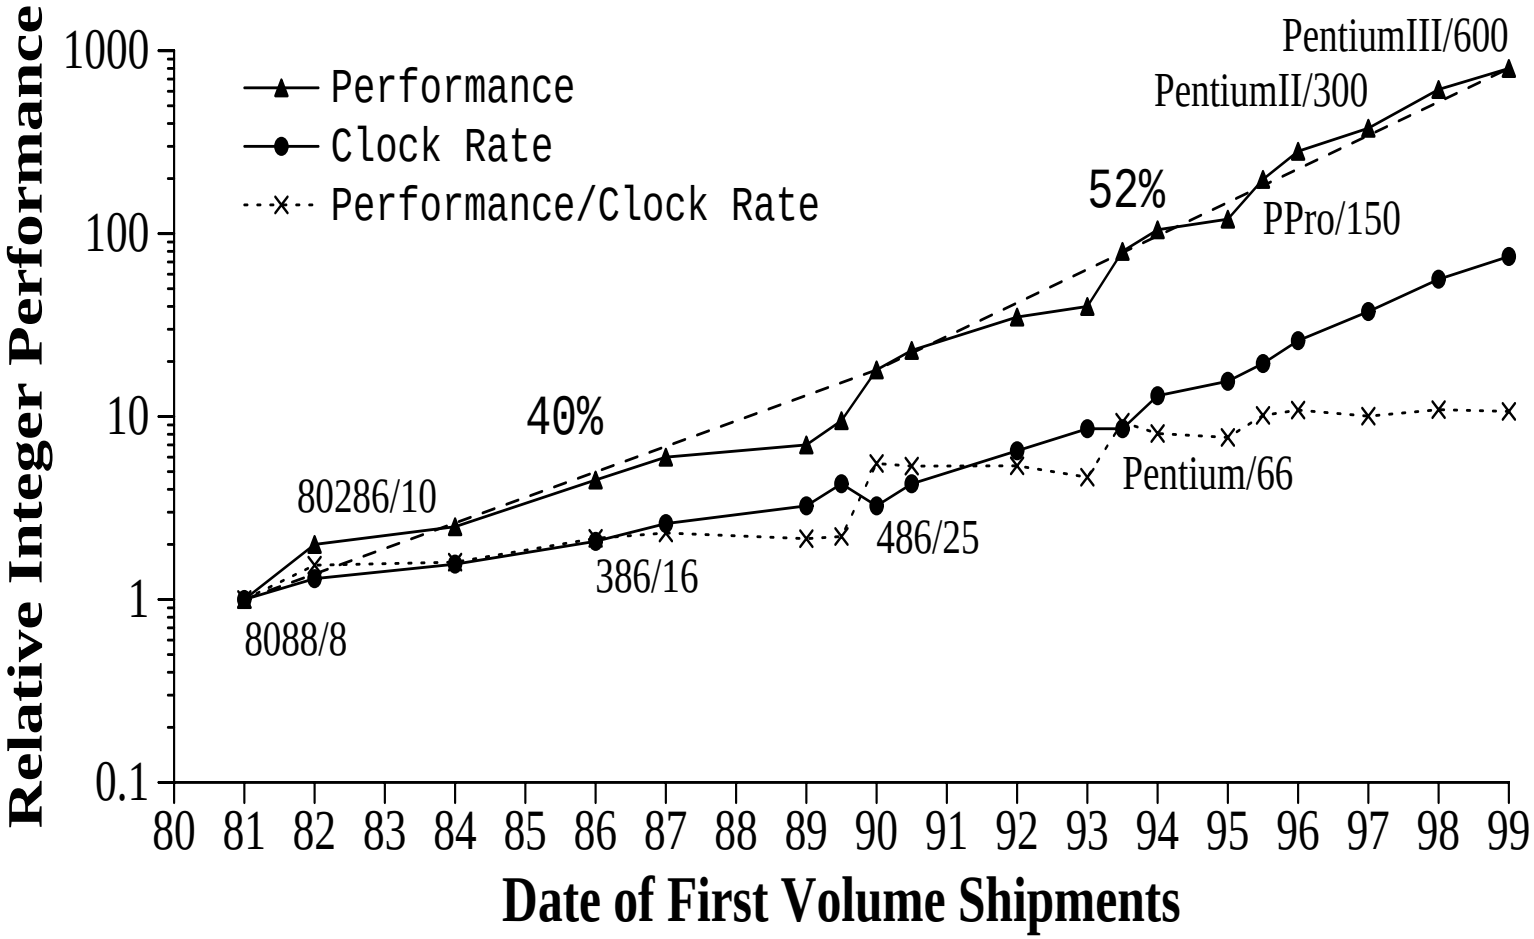
Outline

- Growth in processor performance
- Concepts and performance refiners
- Existing basis: observed events
- Potential future basis: causal relationships
- Examples
- Handling information about causal relationships

Growth in Microprocessor Performance



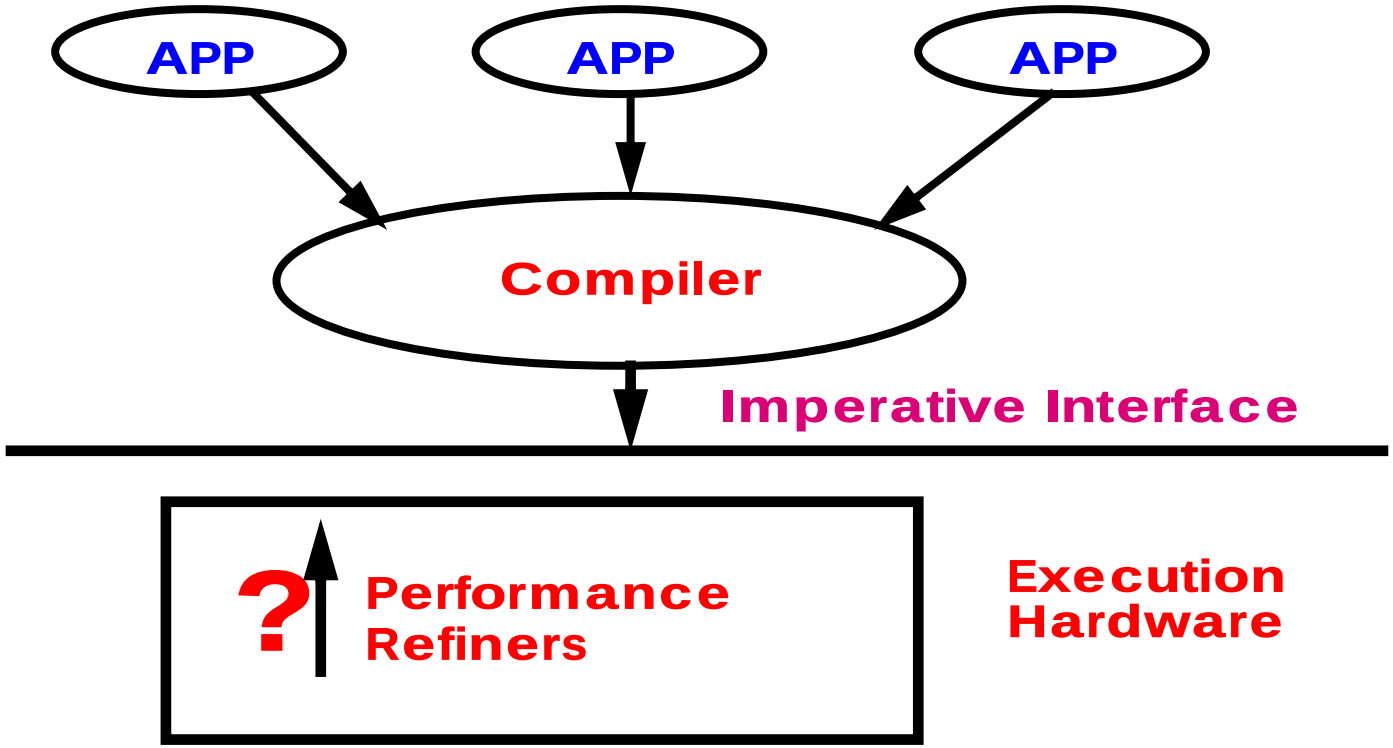
Thanks to Doug Burger and Steve Keckler

Contributors to Performance Growth

- Semiconductor technology
- Architectural and microarchitectural concepts
  - memory hierarchies
  - pipelining
  - out-of-order execution with speculation
  - speculative multithreading
- Concept Enablers/Performance Refiners
  - novel cache elements
  - cache management
  - branch predictors
  - dependence predictors

Software/Hardware Interface and Hardware Role

- Interface is imperative (vs. declarative)
  - \+ results in repeatable execution state
  - \- limited flexibility for changing technology parameters
- Hardware tries to determine program's future actions



Hardware Performance Refiners

- Hardware tries to learn program's intentions
  - Observes program actions (statistical)
  - Uses other information
- Uses information to keep ahead of program's execution
  - make predictions about future outcomes
- Limited amount of hardware limits ability to learn about events

Observed Events: Secondary Information

Secondary information: instruction inputs/outputs

- Examples: branch outcomes, addresses, values
- Properties: spatial/temporal locality, patterns

Current mechanisms almost exclusively based on secondary information and its properties

Problem I: secondary properties may not hold all the time

Problem II: Hard to determine program's future actions

Observations

- Programs have structure (relationships amongst operations)
- Program structure **causes** the **observed** program behavior
- Can we exploit **primary** information, i.e., **causal relationships** in architecture/microarchitecture?
- Good model for predicting about future outcomes might be selected parts of the program!

Primary Information: Program Structure

Primary information: relationships amongst operations

- Examples: control dependences, data dependences
- Properties:
  - **temporal stability:** program is invariant (strong)
  - **causality:** causes all observed secondary behavior

Problems Considered

- Branch Prediction
- Scheduling memory operations in OOO machines
- Inter-operation communication through memory
- Communication in multiprocessors
- Prefetching linked data structures

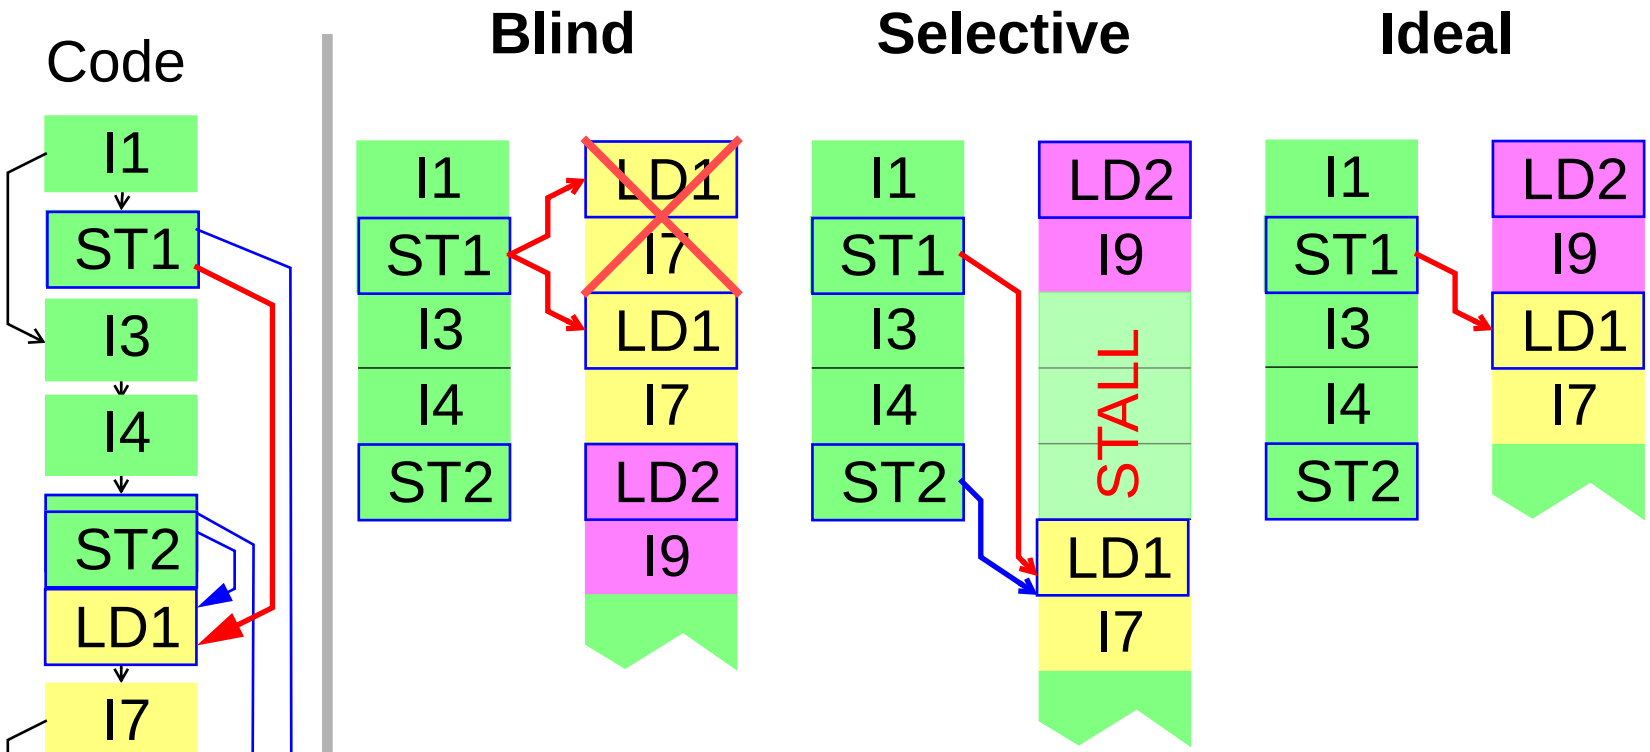
Problem: Branch Prediction

- Predict the outcome of a branch instruction (taken or not taken)
- Smith 2-bit predictor: learns about previous branch outcomes
  - observes outcomes of single branch
- Yeh and Patt-type adaptive predictors: branch outcomes correlated with other branch outcomes
  - learn branch correlations
  - Still exploiting an observation, rather than a cause
- Can we exploit primary (causal) information?
  - Yes, but not in this talk (e.g., Farcy (MICRO 98), Roth (ICS'99))

Problem: Scheduling Memory Operations

- OOO instruction scheduler has collections of instructions to schedule, including loads/stores
- When to schedule a load instruction?
  - when it is not dependent on a pending store
    - may be too late
  - speculate no dependence, and recover if incorrect
    - need performance refiner to improve speculation accuracy

Dependence Speculation

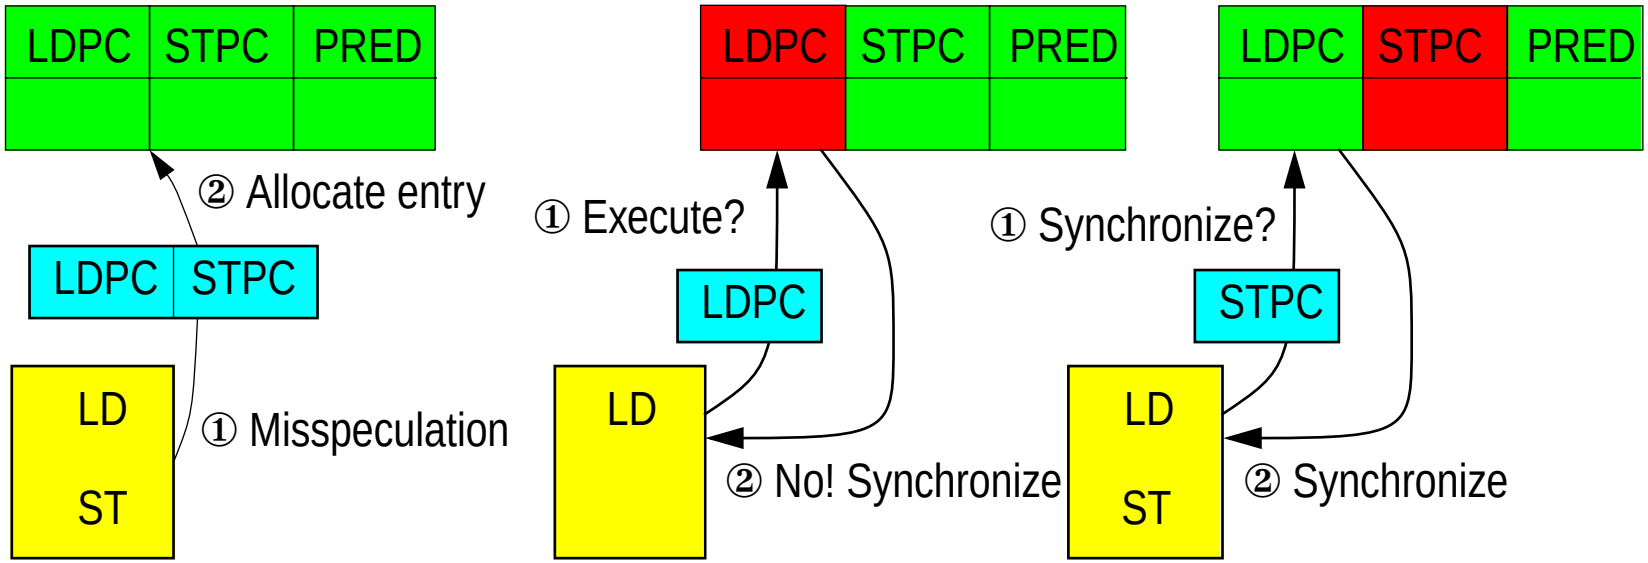


- Selective may perform worse than blind
- Can also perform as well as the ideal
- In practice:
  performance behavior varies

Learning Dependence Relationships

- Dependence: (Load PC, Store PC)
- Temporal locality - Small Working Set.
- Use a small table to: (1). track recent mis-speculations
  (2). Predict dependences

Memory Dependence Prediction Table



Solution Summary

Solution1: use prediction to stall offending loads

- no program structure information required
- not very effective

More Hesson, et. al., 1997

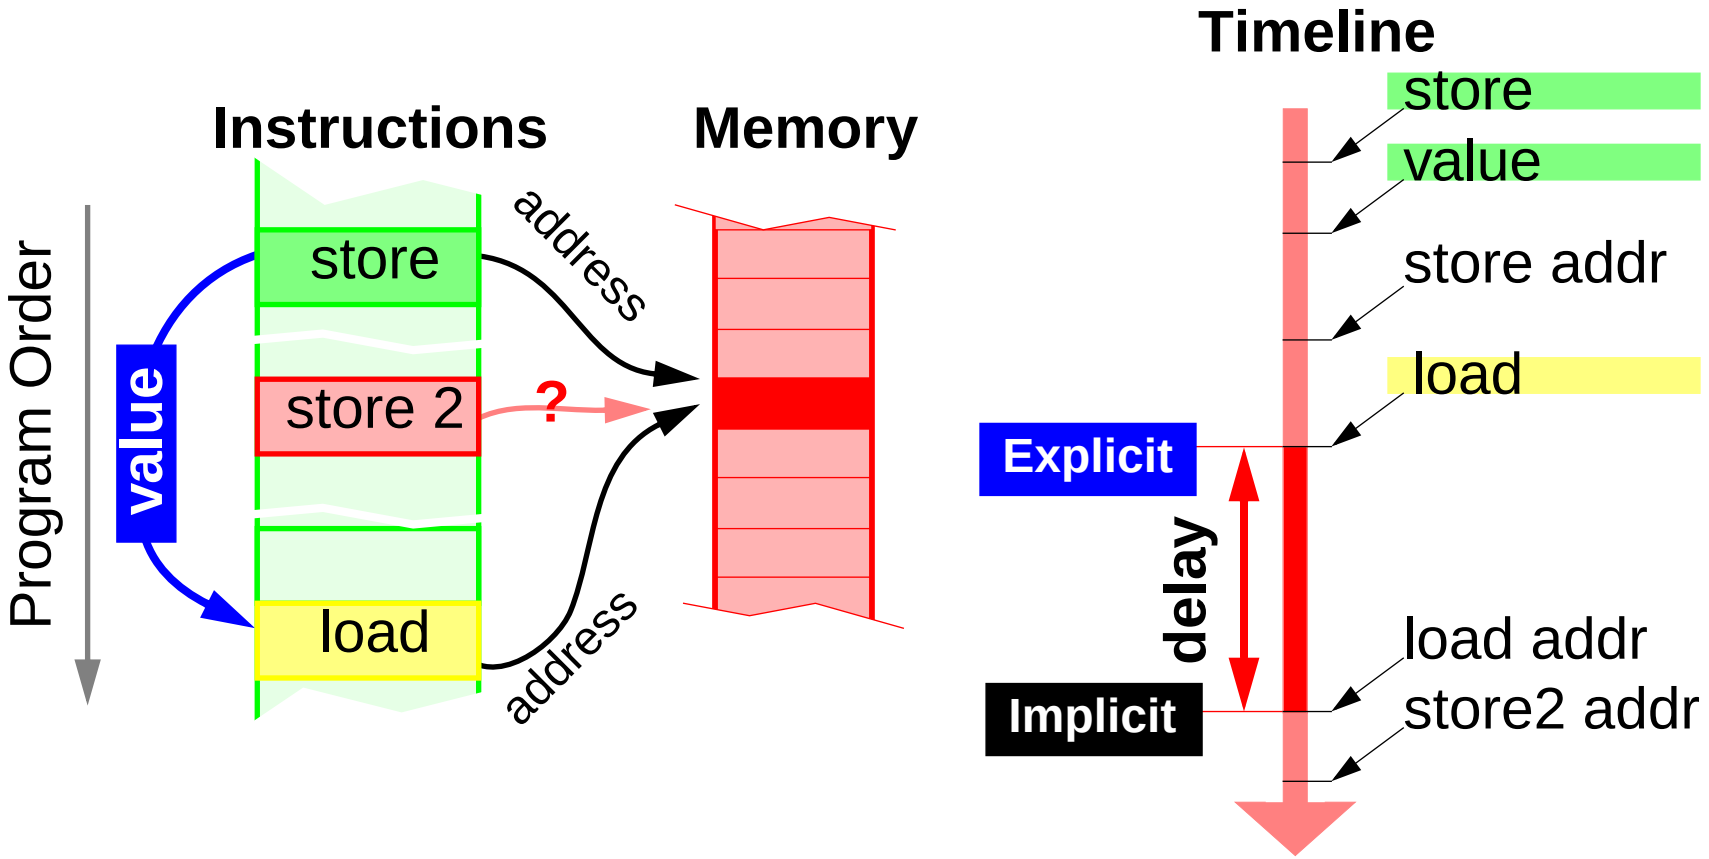
Solution 2: **determine store-load dependences and use to synchronize speculation**

- use program structure
- very effective

More Moshovos, et. al., 1997, Chrysos and Emer 1998

Problem: Communicating Values Through Memory

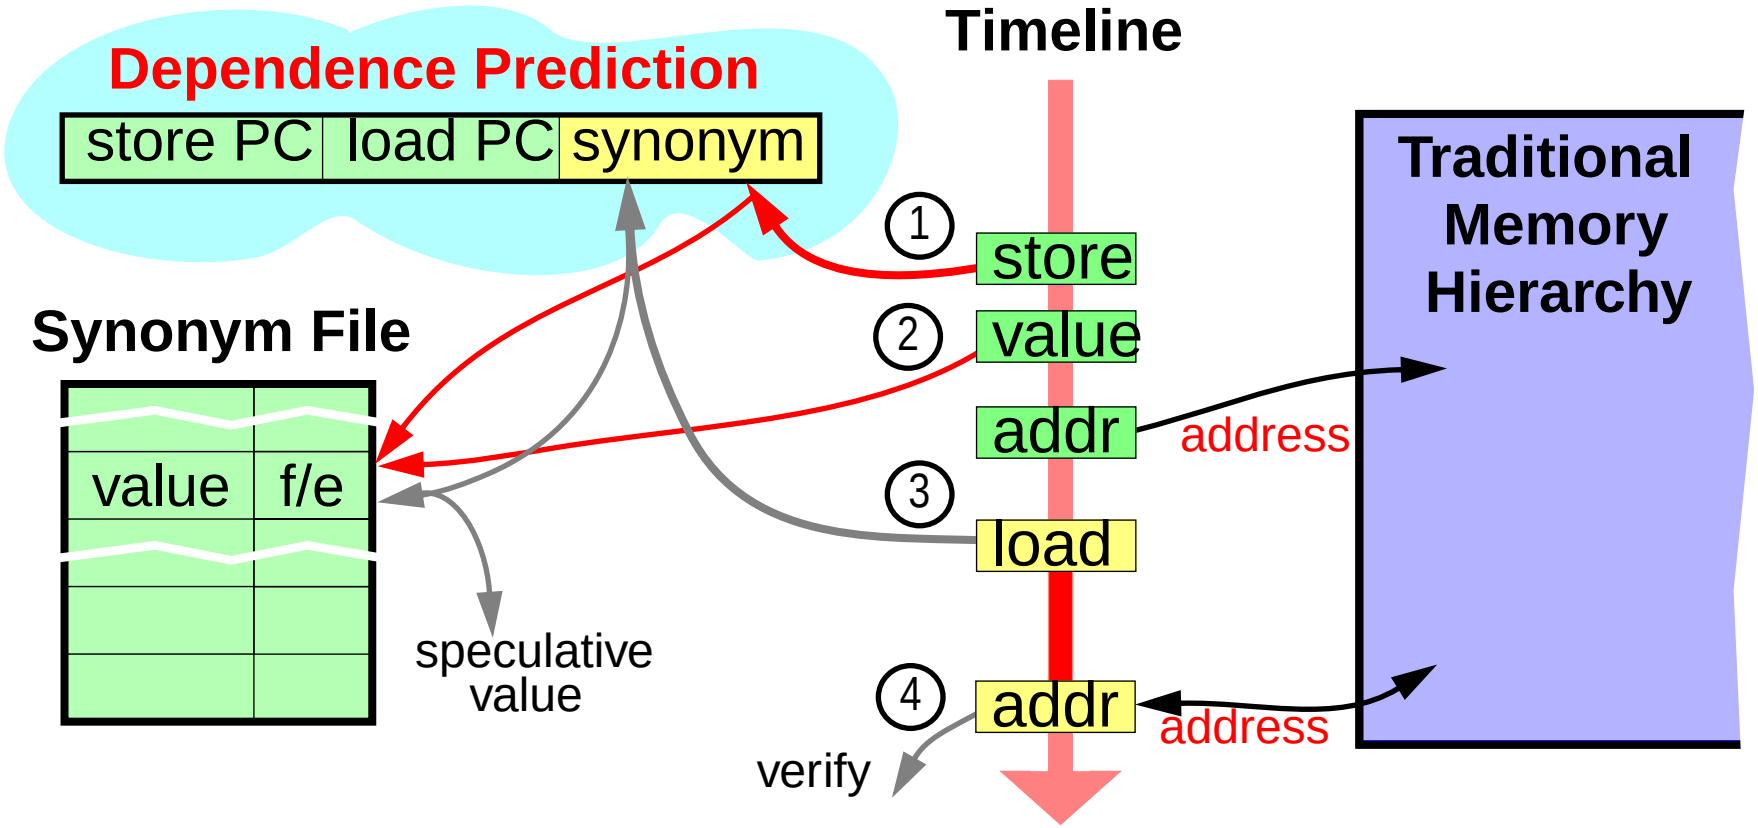
Implicit	Explicit
Delays: 1. Calculate address 2. Establish Dependence	Store - Load: Direct Link **No Delays**



Speculative Memory Cloaking

Dynamically & Transparently convert implicit into explicit

- **Dependence prediction** → direct load-store link: **synonym**
- Speculative and has to be **eventually** verified

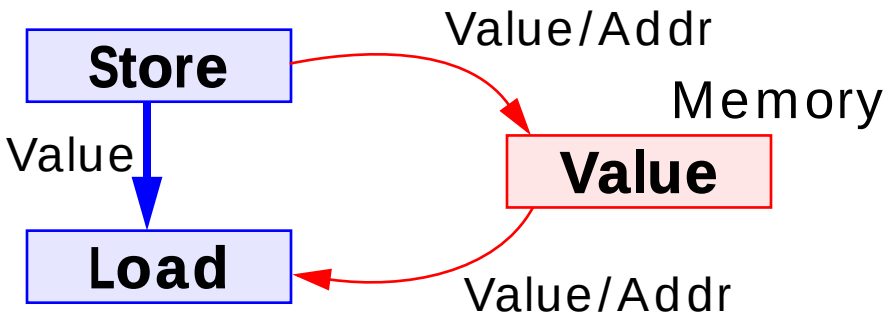


Memory Cloaking Summary

Program structure: **Memory is a communication device for passing values from stores to loads.**
Not random: only certain stores to certain loads

Speculative Memory Cloaking

Link stores to loads explicitly, pass value along link



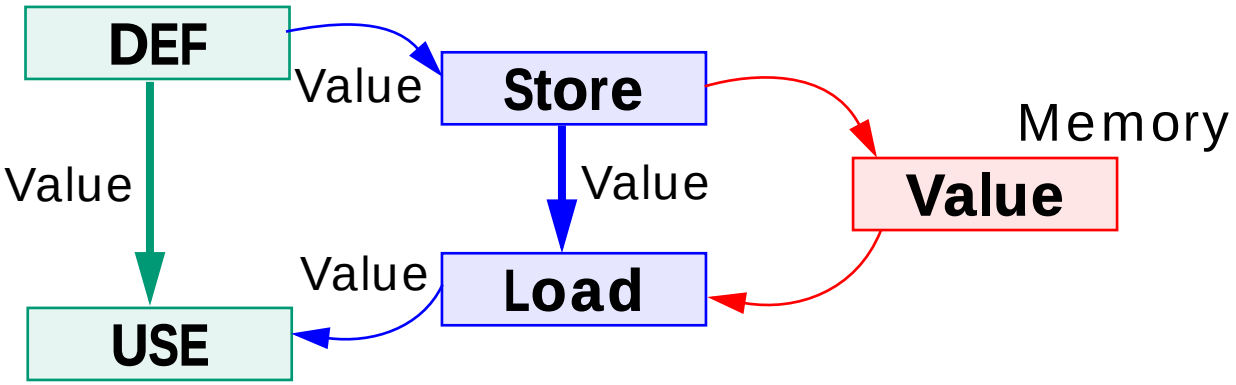
Speculative Memory Bypassing Summary

Program structure: **Loads and stores are used for passing values from one instruction (DEF) to another (USE).**

Via memory? (maybe not, can do it directly)

Speculative Memory Bypassing

Collapse DEF-store, store-load, load-USE links into a direct DEF-USE link



More: Moshovos & Sohi, Tyson & Austin, MICRO-30

Problem: Fast Communication in Shared memory MP's

Problem: Optimize CC protocols for sharing patterns

So far: Detect patterns using address attributes

- Track state proportional in size to data (big)
- Little predictive power

Program structure: **Sharing pattern property of program, not data**

Detect using instruction relationships

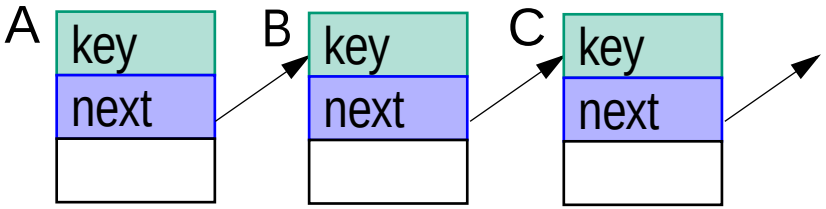
- Track state proportional in size to program (small)
- Great predictive power, works much better

More: [Kaxiras, PhD Thesis, HPCA99]

Problem: Prefetching Linked Data Structures

Linked Data Structures (LDS): pointer-based

- Lists, trees, graphs, etc.
- Prevalent: simulators, compilers, databases, OO-progs



```
for (l = list; l; l = l->next)
    if (l->key == key)
        process(l);
```

Pointer Load

As if memory latency wasn't a problem already...

Pointer Chasing Problem

→ **Pointer loads serialized**

→ **Latencies add**

Solution: Make sure latencies are short → Prefetch

Potential Solution

v /**Pre.fetch**/ := Issue loads as early as possible
(as soon as address is ready)

First reaction: Try to predict addresses

- Array: See A[0], A[1], A[2] → predict A[3]
- LDS: See A, B, C → predict ?

Mechanics I - Overview

Observation: some piece of code must be producing addresses/traversing structure

Step 1. Examine running program, learn dependences, isolate code thread

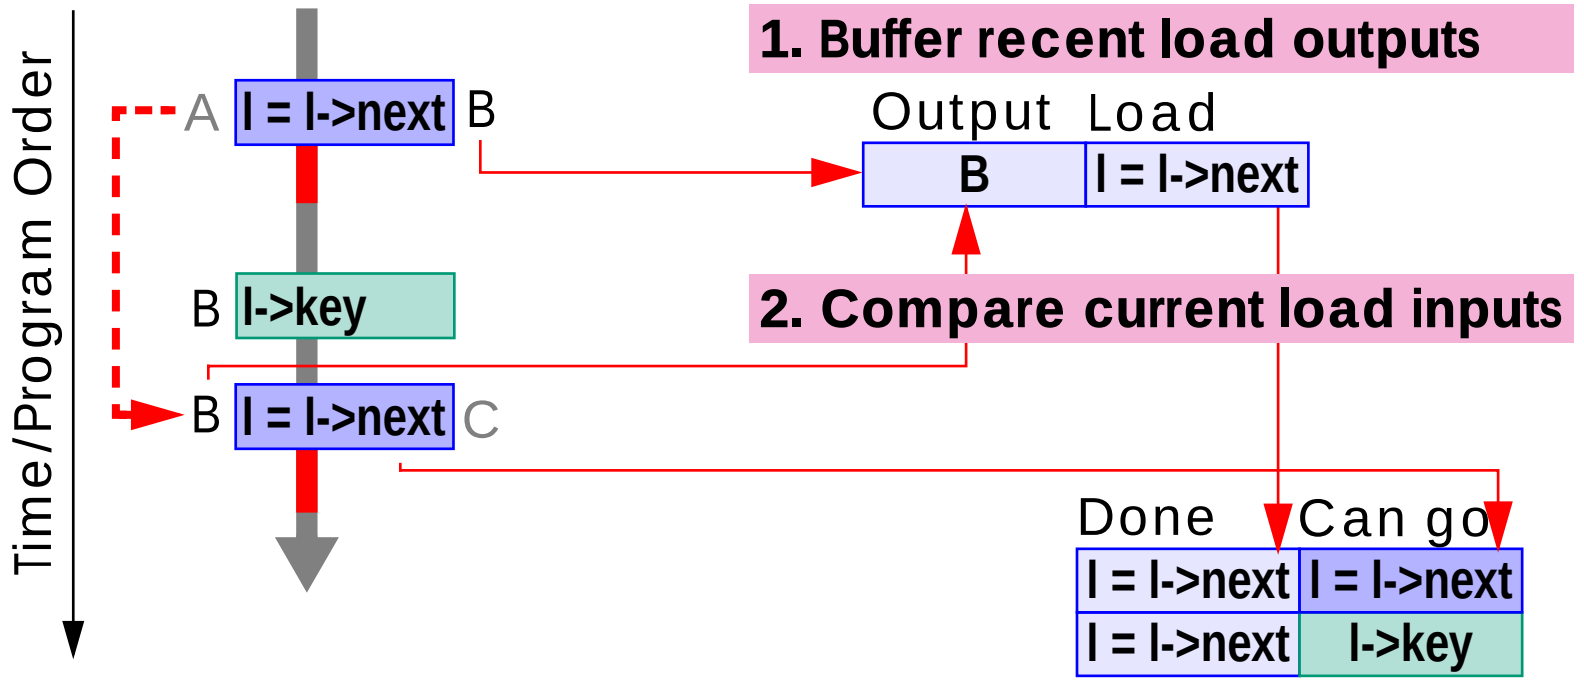
Step 2. Pre-execute code to launch prefetches

More: [Roth, Moshovos & Sohi, ASPLOS-8, ISCA99]

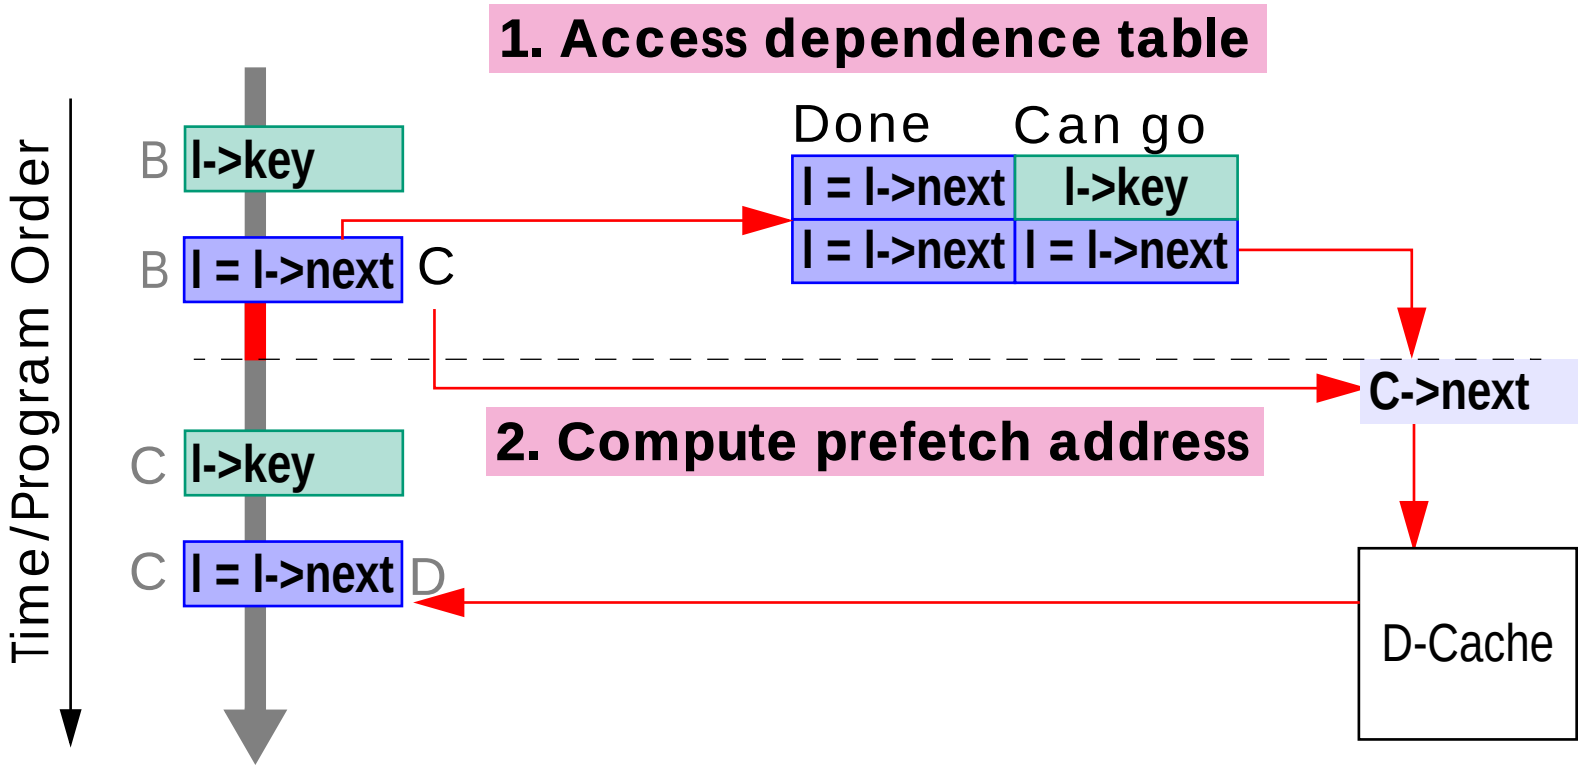
Mechanics II - Learning Dependences

Establish (dynamic) dependence between (static) loads

Use values exchanged to do this



Mechanics III - Prefetching



Summary and More Questions

- Several applications for very limited program structure information
- How should this information be gathered, managed, and provided to the hardware performance refiners?
  - described techniques used hardware
  - software knows this information trivially
- How can software get involved?
  - 4 models

Model 1 for Software Involvement

- Hardware extracts program structure information. Represents internally in declarative manner
  - \- Likely to have limited abilities; much more possible with software
  - \+ may be only practical option

Model 2 for Software Involvement

- Software has program structure information available trivially
- Use information to develop mandate for hardware
- Express mandate in imperative language
- Does not work with a collection of hardware platforms
    - balance keeps shifting with disparate rates of changes in technology
- Been there, done that

Model 3 for Software Involvement

- Express computation as a dataflow graph
  - dependence relationships available to hardware
- Should this be done? NO
  - No repeatable state for program execution
- Advantages of repeatable state
  - Easy to write debug software (debatable).
  - Easy to design, build, verify hardware (not debatable

Model 4 for Software Involvement

- Express computation in imperative manner
  - repeatable state
- Provide advisory program structure information in a declarative manner
- Overheads for doing so
  - provide information judiciously

Research Issues

For a particular optimization

- What program structure information is required?
- How do we represent this information?
- How do we collect and manage this information?

More broadly

- Where can we apply program structure?
- Is there a larger framework?
- What is general purpose program structure?
- Implementations?

Reseach Issues II: Implementations

Hardware only

Software to hardware

- Compiler has all kinds of program information
- How to express it? Instruction-like things awkward
- Where and how much to express?

Software/hardware hybrids

Summary

- Architectural/microarchitectural innovations (performance refiners) will be critical to future processor performance growth
- Current performance refiners are based on observed events
- Future performance enablers likely to need program structure to reason about program's future actions
- Several examples presented; many others
- Several research issues in gathering, conveying, maintaining, and managing such information
